Let p = LnR, where L and R denote the strings on the left and on the right of the maximal entry n.

Then

$$s(p)=s(L)s(R)n,$$

and this recursively defines the stack sorting operation.

### Decreasing binary trees

In the tree T(p) of the permutation p = LnR, the root has label n, the entries of L are in the left subtree, and the entries of R are in the right subtree. These subtrees are defined recursively by the same rule.

For t = 1 and t = 2, log-concavity is routine to prove because of the explicit formulae known for the numbers  $W_t(n, k)$ .

The real root property is not obvious, but is known to be true, by the work of Brenti and Brändén.

The conjecture is open for all values of  $t \in [3, n-3]$ .

#### Conjecture

For all n, the sequence  $W_1(n)$ ,  $W_2(n)$ ,  $W_3(n)$ ,  $\cdots$  is log-concave.
