LEIBNIZ-INSTITUTE

# Distinctions: Physics & Dynamics

Dynamics	Physics
Grid-scale	Subgrid-scale
Energy conversions	Energy conversions end up
forth and back	in unavailable energy pool
Reversible processes	Irreversible processes
No internal entropy production	Positive internal entropy production

The last three lines hold for the continuous moist equations that include viscous and molecular scales (Navier Stokes eq.).

#### Does the distinction hold for the discretized coarse-grained equations, too?

I would wish: Yes

Modeling tradition says: No

Almut Gassmann Institute of Atmospheric Physics, Kühlungsborn, Germany

# Continuous equations as a benchmark for coarse-grained model equations?

#### **Continuous equations**

Thermal conduction Diffusive fluxes of constituents Viscous stresses Phase changes Radiation (line by line)

#### **Coarse-grained equations**

Turbulent heat flux Turbulent/sedimentation fluxes Turbulent stresses Subgrid phase changes, clouds Simplified Radiation

1 D > 4 D >

Known coefficients

Unknown coefficients have to be parameterized

At the present stage: stick to continuous eq. as benchmark and highlight energy conversions and consequences of enforced positive internal entropy production for the flux formulations.

Almut Gassmann Institute of Atmospheric Physics, Kühlungsborn, Germany Energy conversions and internal entropy production in a moist atmosphere

Continuous equ. as benchmark		
0000000		

## Air constituents

$$\partial_t \varrho_i = -\nabla \cdot (\mathbf{v}_i \varrho_i) + I_i = -\nabla \cdot (\mathbf{v} \varrho_i + \mathbf{J}_i) + I_i$$

• Barycentric velocity 
$$\mathbf{v} = \sum_i \varrho_i \mathbf{v}_i / \sum_i \varrho_i$$
.

- Total mass  $\varrho = \sum_{i} \varrho_{i}$  conservation:  $\partial_{t} \varrho = -\nabla \cdot (\varrho \mathbf{v})$
- ▶ Diffusive flux  $J_i = \varrho_i(v_i v)$ .  $\sum_i J_i = 0$  follows from definition. Fluxes include precipitation and turbulent fluxes.

Surface 
$$\mathbf{v}_{surf} \neq 0$$
, e.g.  $\mathbf{v}_{surf} = \frac{\mathbf{J}_{precip} + \mathbf{J}_{v}}{\varrho - \varrho_{v} - \varrho_{precip}}$ 

- Conversion rates are mass conserving  $\sum_i I_i = 0$ .
- All air constituents have their thermodynamic properties  $c_{pi} = c_{vi} + R_i$ .
- All air constituents have the same temperature T.

Almut Gassmann Institute of Atmospheric Physics, Kühlungsborn, Germany

## Different prognostic formulations for constituents

Densities  $\varrho_i$ :

$$\partial_t \varrho_i = -\nabla \cdot (\mathbf{v} \varrho_i) + I_i - \nabla \cdot \mathbf{J}_i$$

Specific contents  $q_i = \varrho_i / \varrho$ :

$$\partial_t q_i = -\mathbf{v} \cdot \nabla q_i + \frac{1}{\varrho} I_i - \frac{1}{\varrho} \nabla \cdot \mathbf{J}_i$$

Mixing ratios  $r_i = \varrho_i / \varrho_d$ :

$$\partial_t r_i = -\mathbf{v} \cdot \nabla r_i + \frac{1}{\varrho_d} I_i - \frac{1+r_i}{\varrho_d} \nabla \cdot \mathbf{J}_i - \frac{r_i}{\varrho_d} \nabla \cdot \sum_{j \ni (i,d)} \mathbf{J}_j$$

Almut Gassmann Institute of Atmospheric Physics, Kühlungsborn, Germany

## Mechanical energy equations

Momentum equation

$$d_t \mathbf{v} = \partial_t \mathbf{v} + \nabla \frac{\mathbf{v}^2}{2} + (\nabla \times \mathbf{v}) \times \mathbf{v} = -2\mathbf{\Omega} \times \mathbf{v} - \frac{1}{\varrho} \nabla \rho - \nabla \Phi - \frac{1}{\varrho} \nabla \cdot \underline{\tau}$$

Dot momentum equation with  $\rho \mathbf{v}$ , Note:  $\mathbf{v} \cdot (\mathbf{A} \times \mathbf{v}) = 0$  $\Rightarrow$  Kinetic energy equation,  $K = \mathbf{v}^2/2$ 

$$\varrho d_t K = \partial_t (\varrho K) + \nabla \cdot (\varrho \mathbf{v} K) = \underbrace{-\nabla \cdot (\rho \mathbf{v}) + \rho \nabla \cdot \mathbf{v}}_{=-\mathbf{v} \cdot \nabla \rho} - \varrho \mathbf{v} \cdot \nabla \Phi - \nabla \cdot (\underline{\tau} \cdot \mathbf{v}) \underbrace{+\underline{\tau} \cdot \nabla \mathbf{v}}_{=-\varepsilon_{fric}}$$

& Potential energy ( $\Phi = gz$ ) equation

$$\varrho d_t \Phi = \partial_t (\varrho \Phi) + \nabla \cdot (\varrho \mathbf{v} \Phi) = + \varrho \mathbf{v} \cdot \nabla \Phi$$

Almut Gassmann Institute of Atmospheric Physics, Kühlungsborn, Germany

Continuous equ. as benchmark		
00000000		

## Internal energy equation

Repeat mechanical energy equation from last slide

$$\rho d_t(K + \Phi) = -\nabla \cdot (\rho \mathbf{v} + \underline{\tau} \cdot \mathbf{v}) + p \nabla \cdot \mathbf{v} - \varepsilon_{fric}$$

Internal energy (specific symbol: u) equation is postulated from enforcing total energy conservation and allowing for further redistributions of heat

$$\varrho d_t u = -\boldsymbol{p} \nabla \cdot \mathbf{v} + \varepsilon_{fric} - \nabla \cdot (\mathbf{R} + \mathbf{W})$$

• 
$$u = \sum_{i} u_{i}q_{i}$$
 and  $u_{i} = u_{i,0} + c_{v,i}(T - T_{0})$ 

- R: radiation flux
- ▶  $\mathbf{W} = \mathbf{J}_s + \sum_i h_i \mathbf{J}_i$ : total heat flux is comprised of sensible heat flux  $\mathbf{J}_s$  and the heat transported with the constituents  $\sum_i h_i \mathbf{J}_i$ . → Latent heat flux (?)
- $h_i = h_{i,0} + c_{p,i}(T T_0)$  are the enthalpies of the constituents.

Almut Gassmann Institute of Atmospheric Physics, Kühlungsborn, Germany

## The material entropy budget equation

Internal energy U depends on  $(V,S,Q_i)$ . Gibbs relation reads then

$$\varrho d_t u = -p \nabla \cdot \mathbf{v} + T \varrho d_t s + \sum_i \mu_i \varrho d_t q_i$$

with  $\mu_i = h_i - Ts_i$  the chemical potentials. Insert now internal energy equation and constituent equations. Distinguish entropy flux divergences and internal entropy production

$$\varrho d_t s = -\nabla \cdot \left(\frac{\mathbf{J}_s}{T} + \sum_i s_i \mathbf{J}_i\right) + \underbrace{\frac{\varepsilon_{fric} - \mathbf{J}_s / T \cdot \nabla T - \sum_i \mathbf{J}_i \cdot \nabla \mu_i |_T - \sum_i l_i \mu_i}{T}}_{\text{internal entropy production}}$$

Red terms are energy dissipation rates.

Almut Gassmann Institute of Atmospheric Physics, Kühlungsborn, Germany

Continuous equ. as benchmark		
0000000		

### Consequences of the material entropy budget equation

$$\varrho d_t s = -\nabla \cdot \left( \frac{\mathbf{J}_s}{T} + \sum_i s_i \mathbf{J}_i \right) + \frac{\varepsilon_{fric} - \mathbf{J}_s / T \cdot \nabla T - \sum_i \mathbf{J}_i \cdot \nabla \mu_i |_T - \sum_i l_i \mu_i}{T}$$

2nd law: Each of the dissipation terms must be positive for itself (Curie's principle: no coupling between processes of different tensor degree). This puts constraints on the fluxes  $\underline{\tau}$ ,  $J_s$ ,  $J_i$  and  $I_i$ .

•  $\varepsilon_{fric} = -\underline{\tau} \cdot \cdot \nabla \mathbf{v} > 0$  constraints the tensor shape of  $\underline{\tau}$ 

►  $\varepsilon_{th} = -\mathbf{J}_s/T \cdot \nabla T > 0$  constraints  $\mathbf{J}_s \propto -\nabla T$  being downgradient T ,

•  $\varepsilon_{mix} = -\sum_{i} \mathbf{J}_{i} \cdot \nabla \mu_{i} |_{T} > 0$  reflects the mixing of air constituents

•  $\varepsilon_{pc} = -\sum_{i} I_i \mu_i > 0$  states the direction of phase changes

The constraints organize the direction of fluxes, but not the strengths. The task of parameterization should thus only be to tune the strengths of those fluxes.  $( \Box ) ( \Box )$ 

Almut Gassmann Institute of Atmospheric Physics, Kühlungsborn, Germany

# Constraints on numerical operators(1)

In all manipulations, for the energy and for the entropy budget equations, the following operators are involved:

- ▶  $\mathbf{v} \cdot (\mathbf{A} \times \mathbf{v}) = 0$  This requires the Lamb transformed momentum advection term  $-\mathbf{v} \cdot \nabla \mathbf{v} = -\nabla K (\nabla \times \mathbf{v}) \times \mathbf{v}$ .
- ▶  $\nabla \cdot (\psi \mathbf{w}) = \psi \nabla \cdot \mathbf{w} + \mathbf{w} \cdot \nabla \psi$ . Gradient and divergence operators are not independent.
- -v · ∇<u>τ</u> = −∇ · (<u>τ</u> · v) + <u>τ</u> · ·∇v is a challenge to be formulated in arbitrary coordinates (on hexagonal C-grid: ref. Gassmann (2018), QJRMS).

Almut Gassmann Institute of Atmospheric Physics, Kühlungsborn, Germany

Continuous equ. as benchmark	Structural constraints			
0000000	000	00000000	00000	000

## Constraints on numerical operators(2)

Poisson brackets implicitly include  $\mathbf{v} \cdot (\mathbf{A} \times \mathbf{v}) = 0$  and  $-\psi \nabla \cdot \mathbf{w} - (-\nabla \cdot (\psi \mathbf{w}) + \mathbf{w} \cdot \nabla \psi) = 0$ 

$$\begin{split} \{\mathcal{F},\mathcal{H}\} &= -\int_{V} \frac{\delta \mathcal{F}}{\delta \mathbf{v}} \cdot \left(\frac{\boldsymbol{\omega}_{a}}{\varrho} \times \frac{\delta \mathcal{H}}{\delta \mathbf{v}}\right) dV \\ &- \int_{V} \left(\frac{\delta \mathcal{F}}{\delta \varrho} \nabla \cdot \frac{\delta \mathcal{H}}{\delta \mathbf{v}} - \frac{\delta \mathcal{H}}{\delta \varrho} \nabla \cdot \frac{\delta \mathcal{F}}{\delta \mathbf{v}}\right) dV \\ &- \int_{V} \left(\frac{\delta \mathcal{F}}{\delta \tilde{\theta}} \nabla \cdot \left(\theta \frac{\delta \mathcal{H}}{\partial \mathbf{v}}\right) - \frac{\delta \mathcal{H}}{\delta \tilde{\theta}} \nabla \cdot \left(\theta \frac{\delta \mathcal{F}}{\delta \mathbf{v}}\right)\right) dV \end{split}$$

Main advantage: Formulate the divergence in terrain-following coords with contravariant flux components, and the respective (pressure!) gradient in terrain-following coords can be deduced.

Almut Gassmann Institute of Atmospheric Physics, Kühlungsborn, Germany

## Constraints on prognostic thermodynamic equation

The energy and the entropy budgets equation shall be derivable from the prognostic model equations.  $\label{eq:prognostic}$ 

 $\Rightarrow$  Approximations are not allowed in the prognostic equations themselves.

Temperature eq. for a height-based vertical coord. formulation:

$$\hat{c}_{v}\varrho d_{t}T = -p\nabla \cdot \mathbf{v} + \varepsilon_{fric} + T\nabla \cdot \sum_{i} \mathbf{J}_{i} c_{v,i} - \sum_{i} (\widetilde{h_{0,i}} + c_{v,i}T) I_{i} - \nabla \cdot (\mathbf{R} + \mathbf{J}_{s} + \sum_{i} c_{\rho,i}T\mathbf{J}_{i})$$

Temperature eq. for a pressure-based vertical coord. formulation:

$$\hat{c}_{p}\varrho d_{t}T = \omega + \varepsilon_{fric} + T\nabla \cdot \sum_{i} \mathbf{J}_{i}c_{p,i} - \sum_{i} (\widetilde{h_{0,i}} + c_{p,i}T)I_{i} - \nabla \cdot (\mathbf{R} + \mathbf{J}_{s} + \sum_{i} c_{p,i}T\mathbf{J}_{i})$$

$$\hat{c}_{v} = \sum_{i} c_{v,i}q_{i}, \ \hat{c}_{p} = \sum_{i} c_{p,i}q_{i}, \ \widetilde{h_{0,i}} = h_{0,i} - c_{p,i}T_{0}, \ \omega = d_{t}p$$

Almut Gassmann Institute of Atmospheric Physics, Kühlungsborn, Germany

# 2nd law constraints

#### Repeated from a previous slide

2nd law puts constraints on the fluxes  $\underline{\tau}$ ,  $\mathbf{J}_s$ ,  $\mathbf{J}_i$  and  $l_i$ .

- $\varepsilon_{fric} = -\underline{\tau} \cdot \nabla \mathbf{v} > 0$  constraints the tensor shape of  $\underline{\tau}$
- ►  $\varepsilon_{th} = -\mathbf{J}_s/T \cdot \nabla T > 0$  constraints  $\mathbf{J}_s \propto -\nabla T$  being downgradient T,
- $\varepsilon_{mix} = -\sum_{i} \mathbf{J}_{i} \cdot \nabla \mu_{i} |_{T} > 0$  reflects the mixing of air constituents

•  $\varepsilon_{pc} = -\sum_{i} l_{i}\mu_{i} > 0$  states the direction of phase changes The constraints organize the direction of fluxes, but not the strengths. The task of parameterization should thus be the tuning of the strengths of those fluxes.

00000000 000 000 000000 0000 000	Continuous equ. as benchmark		2nd law constraints		
	0000000	000	00000000	00000	000

### Momentum diffusion tensor

Constraint:  $\varepsilon_{fric} = -\underline{\tau} \cdot \nabla \mathbf{v} > 0. \Rightarrow$  Required tensor formulation:

$$\underline{\tau} = -\varrho \begin{pmatrix} K_h(\partial_x u - \partial_y v) + & K_h(\partial_y u + \partial_x v) & K_v(\partial_z u + \partial_x w) \\ K_v(\frac{1}{3}D_h - \frac{2}{3}\partial_z w) & K_h(\partial_y v - \partial_x u) + & \\ K_h(\partial_y u + \partial_x v) & K_v(\frac{1}{3}D_h - \frac{2}{3}\partial_z w) & K_v(\partial_z v + \partial_y w) \\ K_v(\partial_z u + \partial_x w) & K_v(\partial_z v + \partial_y w) & K_v(\frac{4}{3}\partial_z w - \frac{2}{3}D_h) \end{pmatrix}.$$

- Tensor is invariant to rotations of coords in the horizontal plane.
- Tensor allows for anisotropic diffusion.
- Hydrostatic model omits last column, horizontal w-derivatives in the last row, and K<sub>v</sub>-terms on the trace.
- Optionally add a divergence damping  $-\rho K_d \nabla \cdot \mathbf{v}$  on the trace.

Parameterization scheme must deliver positive  $K_v$ ,  $K_h$ , and  $K_{udviz.ustrutter}$ 

Almut Gassmann Institute of Atmospheric Physics, Kühlungsborn, Germany

Continuous equ. as benchmark	2nd law constraints	

# Heat flux (1)

Almut G

Constraint  $\varepsilon_{th} = -\mathbf{J}_s/T \cdot \nabla T > 0$ .  $\Rightarrow$  Required heat flux formulation:

$$\mathbf{J}_{s} = -c_{p}\varrho \mathbf{\underline{K}}_{T} \cdot \nabla T$$

- Compare to common practice J<sup>z</sup><sub>s</sub> = −c<sub>p</sub> ρK<sub>θ</sub>Π(∂<sub>z</sub>θ − γ), which is not always downgradient T.
- Countergradient or EDMF-fluxes correct the direction of the downgradient θ-flux to be more compatible with the downgradient *T*-flux.
- Explanation: Interpret the TKE to be comprised in the internal energy reservoir (non-resolved energy!)

$$\underbrace{\partial_{t}(c_{\nu}\varrho T)|_{sub}}_{c_{\rho}\Pi\partial_{t}(\varrho\theta)|_{sub}} = -\partial_{z}(-c_{\rho}\Pi\varrho K_{\theta}\partial_{z}\theta) + \underbrace{\rho K_{\theta}N^{2}}_{\Delta E_{int}} - \underbrace{\rho K_{\theta}N^{2}}_{\Delta E_{kin}} - \partial_{z}(-\varrho K_{tke}\partial_{z}k_{e}) + \varepsilon_{sh}$$

$$\underbrace{= -c_{\rho}\Pi\partial_{z}(-\varrho K_{\theta}\partial_{z}\theta)}_{rhs of TKE-equation}$$

$$\underbrace{= -c_{\rho}\Pi\partial_{z}(-\varrho K_{\theta}\partial_{z}\theta)}_{rhs of TKE-equation}$$

Continuous equ. as benchmark	Structural constraints 000	2nd law constraints	Interference with numerics	Mail questions
Heat flux (2)				

$$\underbrace{\frac{\partial_t (c_v \varrho T)|_{sub}}{c_p \Pi \partial_t (\varrho \theta)|_{sub}}}_{=-c_p \Pi \varrho K_\theta \partial_z \theta) + \underbrace{\varrho K_\theta N^2}_{\Delta E_{int}} \underbrace{-\varrho K_\theta N^2}_{\Delta E_{kin}} - \frac{\partial_z (-\varrho K_{tke} \partial_z k_e) + \varepsilon_{sh}}{(c_p \Pi \partial_z (-\varrho K_\theta \partial_z \theta))}$$

$$\underbrace{\frac{\partial_t (c_v \varrho T)|_{sub}}{\partial_t (c_v \varrho T)|_{sub}} = -\partial_z (-c_p \Pi \varrho K_\theta (\partial_z \theta + \frac{K_{tke} \partial_z k_e}{c_p \Pi K_\theta})) + \underbrace{\varepsilon_{sh}}_{=\varepsilon_{fric}}$$

$$\gamma = -\frac{K_{tke} \partial_z k_e}{c_p \Pi K_\theta}.$$

The inclusion of the TKE keeps the heat flux downgradient T in the upper, slightly stable, part of the boundary layer and we have  $J_s^z = -c_p \varrho K_\theta \Pi(\partial_z \theta - \gamma) = -c_p \varrho K_T \partial_z T \text{ with } K_\theta > 0 \text{ and } K_T > 0.$ 

Workshop discussion point: How can we interpret common practice in Letterms of a downgradient *T* formulation?

Almut Gassmann Institute of Atmospheric Physics, Kuhlungsborn, Germany

# Heat flux (3)

- ▶ Previous slides considered the PBL in case of convective or slightly stable conditions. (buoyancy production → TKE → energy transport → energy deposition at higher levels)
- What about heat flux at stable stratification?

#### My opinion:

The question then is not about the heat flux, which is assumed to be tiny and downgradient T (not  $\theta$ ), but about the way we represent wave breaking. For this, the undulation of isentropes must be represented correctly, which requires direct access to the *w*-equation.

#### Hypothesis:

Wave breaking can be modeled with the stress tensor also present in the vertical velocity equation. (Question: What about hydrostatic models?) This allows to represent buoyancy loss (not from TKE, but from the resolved kinetic energy), i.e. kinetic energy of vertical motions gets lost and is deposited as frictional heating in the internal energy reservoir.

Continuous equ. as benchmark	2nd law constraints	
	00000000	

## Turbulent water vapour and dry air fluxes

Constraint:  $\varepsilon_{mix} = -\sum_{i} \mathbf{J}_{i} \cdot \nabla \mu_{i} |_{T} > 0$ 

For ideal gases  $\nabla \mu_i|_T = \frac{1}{\varrho_i} \nabla p_i = R_i T \nabla \ln \varrho_i$  (note  $p_i = R_i \varrho_i T$  and T = const)

• Mixing of dry air and water vapour  $\sum_i \mathbf{J}_i = \mathbf{0} \rightarrow \mathbf{J}_d = -\mathbf{J}_v$ 

 $\blacktriangleright \rightarrow \mathbf{J}_{v} = -\varrho \underline{\mathbf{K}}_{v} \cdot \left(\frac{q_{d} \nabla p_{v} - q_{v} \nabla p_{d}}{p}\right) \neq -\varrho \underline{\mathbf{K}}_{v,trad,q} \cdot \nabla q^{v} \neq -\varrho \underline{\mathbf{K}}_{v,trad,r} \cdot \nabla r^{v}$ 

compare to downgradient q<sub>v</sub>-flux:

$$-\nabla q^{v} = -\frac{R_{d}q_{d} + R_{v}q_{v}}{R_{v}q_{d} + R_{d}q_{v}} \left(\frac{q_{d}\nabla p_{v} - q_{v}\nabla p_{d}}{p}\right) + \frac{(R_{v} - R_{d})q_{v}q_{d}}{R_{d}q^{v} + R_{v}q^{d}}\nabla(\ln \varrho T)$$

Entropy consistent upward directed fluxes are slightly stronger than traditional fluxes, because the water (H<sub>2</sub>O) molecules have a lower weight than dry air (N<sub>2</sub> and O<sub>2</sub>) molecules. The difference seems to be small, but this has to be checked.

# Sedimentation fluxes

Constraint:  $\varepsilon_{mix} = -\sum_{i} \mathbf{J}_{i} \cdot \nabla \mu_{i} |_{\mathcal{T}} > 0$ 

• For precip  $p: \nabla \mu_p |_T = 0.$ 

► The sedimentation flux is parameterized as J<sup>z</sup><sub>p</sub> = -ℓ<sub>p</sub>V<sup>T</sup><sub>p</sub>, with V<sup>T</sup><sub>p</sub> > 0 the terminal velocity of hydrometeors.

$$\blacktriangleright \sum_{i} J_i^z = \sum J_p^z + J_d^z + J_v^z + \sum J_{cloud}^z = 0$$

- ► For non-sedimenting constituents *j*, diffusive vertical velocities have to be assigned  $w_d = w_{d,j} = \frac{\sum_p q_p V_p^T}{1 \sum_p q_p}$ , and their fluxes are  $J_j^z = w_{d,j} \varrho_j$ .
- ► The dissipation is  $\varepsilon_{mix} = -J_d^z \partial_z \mu_d |_T J_v^z \partial_z \mu_v |_T = -w_d \partial_z p = w_d \varrho g > 0$
- ▶ This dissipation ranks highest in magnitude under the various discussed dissipation rates. It is cleanly represented in models only if the w<sub>d</sub> are assigned to the non-sedimenting constituents. (If this is not done explicitly, this w<sub>d</sub> is implicitly seen for dry air if the full density is prognostic.)

## Phase changes

Constraint:  $\varepsilon_{pc} = -\sum_{i} I_{i}\mu_{i} > 0$  states the direction of phase changes. The source terms  $I_{i}$  are scalar fluxes, and thus not related to acessible spatial gradients of some values. Therefore, the coarse-grained numerics is not an issue here.

$$\varepsilon_{pc} = \underbrace{-I_l(\mu_l - \mu_v)}_{-I_f(\mu_f - \mu_v)} \underbrace{-I_f(\mu_f - \mu_v)}_{-I_f(\mu_f - \mu_v)}$$

evaporation/condensation sublimation/deposition

- evaporation/condensation  $\mu_l \mu_v = -R_v T \ln \frac{p_v}{p_v^{\text{sat,}l}}$
- sublimation/deposition  $\mu_f \mu_v = -R_v T \ln \frac{p_v}{p_v^{\text{sat},i}}$
- evaporation/sublimation in sub-saturated environment
- condensation/deposition in super-saturated environment

Almut Gassmann Institute of Atmospheric Physics, Kühlungsborn, Germany

# Reynolds averages

- Reynolds averaged fluxes like  $\overline{\rho w' \psi'}$  for arbitrary scalars  $\psi$  are not needed.
- The correct variable which is diffused downgradient is determined by the second law and is not a free choice of the modeler.
- There are various moist or liquid water aware potential temperature fluxes, and to my knowledge, there is no agreement on which one is the correct one.

It is only clear that the magnitude of the diffusion coeff should depend on vertical (moisture and liquid water aware) buoyancy fluxes.

 Horizontal Reynolds-averaged momentum fluxes or heat fluxes do not necessarily lead to positive dissipation rates. (Finding of my PhD student Bastian Sommerfeld and others.)

Almut Gassmann Institute of Atmospheric Physics, Kühlungsborn, Germany Energy conversions and internal entropy production in a moist atmosphere

# Interference of physics and numerics

#### Different computational spaces spectral space or finite element space $\Leftrightarrow$ grid point space This distinction seems problematic, because it has been demonstrated that the entropy budget equation needs likewise some rules like $-\frac{1}{T}\nabla \cdot \mathbf{J}_s = -\nabla \cdot (\frac{\mathbf{J}_s}{T}) - \frac{1}{T^2}\mathbf{J}_s \cdot \nabla T$ with $\mathbf{J}_s \propto -\nabla T$ to be valid. Hence, physics needs the same computational space and the same numerical operators like numerics.

#### Higher order or TVD advection operators

contain purely advective, purely diffusive and also anti-diffusive parts. How do the anti-diffusive parts affect other parts of the equations?

Almut Gassmann Institute of Atmospheric Physics, Kühlungsborn, Germany

# Higher order or TVD advection operators(1)

Common advection schemes:

$$\partial_t(\varrho\psi) = -\frac{1}{\Delta x} (U_{i+1/2} \hat{\psi}_{i+1/2} - U_{i-1/2} \hat{\psi}_{i-1/2})$$

They differ in their approximation to  $\hat{\psi}_{i+1}$ .

The fluxes can be disentangled into an advective and a diffusive part

$$U_{i+1/2}\hat{\psi}_{i+1/2} = U_{i+1/2}(\bar{\psi}_{i+1/2} - \kappa_{i+1/2}\frac{\delta_x\psi_{i+1/2}}{u_{i+1/2}\Delta x})$$

with  $\bar{\psi} = (\psi_i + \psi_{i+1})/2$  and  $\delta_x \psi_{i+1/2} = \psi_{i+1} - \psi_i$ 

Two problems: (i) Is  $\psi$  the right variable to be diffused? (ii) Is K positive?

Almut Gassmann Institute of Atmospheric Physics, Kühlungsborn, Germany

# Higher order or TVD advection operators(2)

Inspect some schemes including flux limiting schemes

Notation:

if 
$$U_{i+1/2} \ge 0$$
:  $r = (\psi_i - \psi_{i-1})/(\psi_{i+1} - \psi_i)$   
if  $U_{i+1/2} < 0$ :  $r = (\psi_{i+2} - \psi_{i+1})/(\psi_{i+1} - \psi_i)$ 

1st order upwind	$\mathcal{K} =  u_{i+1/2}  \Delta x \frac{1}{2}$
3rd order upwind	$K =  u_{i+1/2}  \Delta x \frac{1-r}{6}$
van Leer scheme	$K =  u_{i+1/2} \Delta x \frac{1-r}{2(1+ r )}$

Problem: K is not necessarily positive. This depends on the role of r.

# Selected questions raised in email (1)

#### What is physical understanding of the latent heat flux?

• Total heat flux  $\mathbf{W} = \mathbf{J}_s + \sum_i h_i \mathbf{J}_i$  does not occur explicitly in prognostic temperature equation.

Locally we have because of  $\sum_{i} \mathbf{J}_{i} = 0$ :

 $\sum_{i} h_i \mathbf{J}_i = \mathbf{J}_v (h_v - h_d) + \mathbf{J}_i (h_l - h_d) + \mathbf{J}_f (h_f - h_d)$ , but we do not know the enthalpy differences between dry air and any other H<sub>2</sub>O-constituent. And this setting is physically pointless.

But in the climate mean  $\mathbf{\bar{J}}_{v} = -\mathbf{\bar{J}}_{l} - \mathbf{\bar{J}}_{f}$  and we obtain reasonably well:

Almut Gassmann Institute of Atmospheric Physics, Kühlungsborn, Germany

# Selected questions raised in email (2)

- ► Geometric structures: Well understood for reversible dynamics. Formally less well understood for irreversible dynamics, but we know that the same gradient-divergence compatibilities must hold. → Chris Eldred
- Structures under approximations: For primitive equations (hydrostat. constraint), the group of Thomas Dubos has paved the path. Could be generalized...?
- ► How does turbulence averaging fit into the framework? I think that this is a matter of interpretation, if one can find a relation like  $\overline{\varrho \mathbf{v}'' \psi''} = -\varrho \mathbf{K} \cdot \nabla \chi$  where  $\psi$  is a classical variable and  $\chi$  is a 2nd law conforming variable and K > 0, all is fine.
- Can we find a single set of equations that is used consistently for the entire model? Yes, but this does not prevent us from tuning the magnitude of the coefficients according to the scales.
